

ABSTRACT

A method of parameters to a telephone associated device includes the steps of: (a) receiving a web-page to be used for setting the parameters by accessing from a client terminal (e.g., a personal computer registered by a user) to a web-server via a wide area network, (b) inputting parameter information onto the web-page by operating the client terminal, (c) transmitting the parameter information to the web-server, (d) then transmitting the parameter information to a CTI server via the wide area network, (e) transmitting the information with a DTMF signal or a modem signal from the CTI server to a modem mounted to the telephone associated device and hooked up to a public switched telephone network. This structure allows a user to set various conditions to the telephone associated device based on the parameter information.
